In 2018 NVIDIA released their new RTX GeForce graphics card generation, which are the first consumer-grade GPUs to offer hardware accelerated ray tracing. It is now the question to which extent this new hardware support allows the use of ray tracing in an established game engine. We will use distributed ray tracing (DRT) to render the entirety of Quake III's 3D game world. A naive ray-tracing implementation will, even with modern hardware acceleration through dedicated processors, be too computationally expensive.

- Random subsampling from a list of lights using random values from blue noise textures
- A light culling strategy using a pre-existing potentially visible set
- A denoiser called Adaptive Spatiotemporal Variance-Guided Filtering [1]

This work consisted of the following steps:

1. Refactor Quake III
2. Implement a renderer based on Vulkan
3. Implement distributed ray tracing
4. Implement previously mentioned optimizations

Follow the arrow to the right to see the results after each optimization. The graph on the left shows the required steps to produce one output frame.

The GPU we used to produce these results was a GeForce RTX 2080 Ti running the Quake III level 'q3dm7'. The graph to the right shows the performance captured at different resolutions from the scene shown below.

We can tell from the graph that light culling does a great job at removing unimportant lights. Especially when all lights are used this results in a big performance gain. The denoiser combined with light subsampling (one light) also improves performance a lot, while still being able to produce a solid visual result.

Still, **the most exciting results were** when we combined the denoiser with light culling and subsampling of the lights. This strategy produced the best quality/performance ratio.

A bar chart showing the number of lights per pixel for four different resolutions: 1280 x 720, 1600 x 900, 1920 x 1080, and 2560 x 1440. For each resolution, four bars are shown, representing different denoiser and light culling settings. The values for each bar are labeled on top of them.

Resolution	no denoiser (light culling on, one light per pixel)	denoiser (light culling on, one light per pixel)	no denoiser (light culling on, all lights)	no denoiser (light culling off, all 106 lights)
1280 x 720	2,67	3,47	6,76	35,71
1600 x 900	4,24	4,95	9,9	52,63
1920 x 1080	5,18	6,8	14,08	76,92
2560 x 1440	8,7	11,63	24,39	125
